

TransitLens — Technical Report · TD2026

TransitLens: Real-Time Transit Intelligence, Equity Analysis, and Safety Intelligence Platform for the TTC

Transit Data Conference 2026 – Data Challenge Technical Report Team: TransitLens Live

Prototype: <https://transit-lens.vercel.app/> Source Code Repository:

<https://github.com/adityashoor/TransitLens> Submission Date: May 30, 2026

1. Problem Statement

The Toronto Transit Commission (TTC) serves over 1.7 million daily riders across a network of 150+ bus routes, 11 streetcar lines, and 4 subway lines. Despite generating rich automated data through GTFS-RT feeds, delay incident systems, and open data portals, a persistent gap exists between data availability and operational decision-making.

This project addresses three specific, interlinked problems:

1.1 Bus Bunching Visibility

Bus bunching — the clustering of two or more vehicles on the same route — is one of the most common and passenger-visible service failures in urban transit. The TTC's GTFS-RT feed publishes real-time vehicle positions, yet no public-facing tool synthesises this stream into a live bunching alert. TransitLens detects bunching live using the Haversine formula applied to GTFS-RT vehicle positions, flagging affected route segments within 30-second polling intervals.

1.2 Equity Measurement and Actionability

Toronto's neighbourhoods differ substantially in transit access. Low-density outer suburbs and lower-income communities experience systematically longer waits and lower service frequency. TransitLens computes neighbourhood-level mobility scores, ranks them by severity, and generates service recommendations in operational language.

1.3 Fragmented Safety and Incident Intelligence

TTC delay incident data, Toronto Police KSI collision records, and Vision Zero metrics are published across separate open data portals. TransitLens integrates these streams into a unified safety intelligence view that identifies spatial hotspots and surfaces actionable alerts.

2. Methodology

2.1 System Architecture

TransitLens is a client-side web application built with React 19 and TanStack Router. All data processing occurs in the browser, with a Supabase backend serving pre-processed route and equity data. External open data sources are fetched directly from the browser with graceful fallbacks, ensuring the application remains functional under network degradation.

Browser

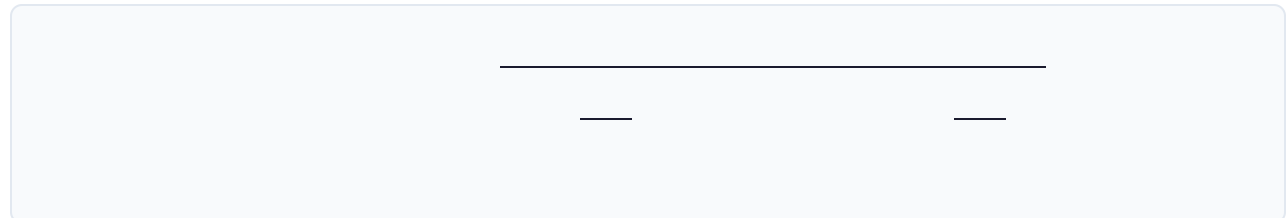

- └─ TanStack Query (caching, deduplication, polling)
- └─ Supabase client (tl_routes, tl_stops, tl_equity, tl_kpi)
- └─ Direct API calls
 - └─ TTC GTFS-RT (bustime.ttc.ca) — 30s polling
 - └─ Toronto Open Data CKAN — bus/subway delay CSVs (streaming)
 - └─ Toronto Police ArcGIS REST — KSI collisions
 - └─ Open-Meteo — 48h weather forecast

2.2 Real-Time Bunching Detection

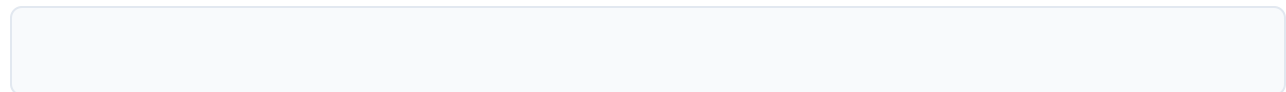

The core algorithmic contribution of TransitLens is a real-time bus bunching detector implemented in `src/hooks/useBunching.ts`.

Algorithm:

1. Vehicle positions are fetched from `bustime.ttc.ca/gtfsrt/vehicles` every 30 seconds.
2. Vehicles are grouped by `route_id`.
3. For each pair of vehicles on the same route, the Haversine great-circle distance is computed:

where

m.

4. Pairs within **200 metres** of each other are flagged as bunching events.
5. Bunching pairs are rendered on the map as amber warning circles at the midpoint between vehicles.

Threshold rationale: A 200 m threshold corresponds to approximately 2–3 bus lengths of gap — operationally negligible for maintaining regular headway — consistent with academic literature

on bunching detection (Bartholdi & Eisenstein, 2012).

2.3 Equity Scoring Methodology

Neighbourhood mobility scores are computed from components stored in the Supabase `tl_equity` table:

Component	Weight	Data source
Stop density (stops/km²)	40%	TTC GTFS stops + neighbourhood polygons
Average wait time (min)	40%	Derived from GTFS schedule headways
Income proxy	20%	Statistics Canada census dissemination areas

Scores are normalised to a 0–100 scale. A score below 40 is classified as a **transit desert**; scores between 40–65 are **underserved**; above 65 is **adequate**. The platform generates data-driven service recommendations comparing each neighbourhood’s score against the TTC’s 15-minute service standard target.

2.4 Safety and Incident Intelligence

Safety data is aggregated from two sources:

TTC Delay Incident Data (Toronto Open Data CKAN): Bus and subway delay records for 2025 are filtered for safety-relevant incident codes including `Collision - TTC`, `Collision - Municipal`, `Emergency Services`, `Investigation`, and `Held By`. Severity is derived from delay minutes: ≥ 20 min → critical, ≥ 8 min → major, < 8 min → minor.

Toronto Police KSI Dataset (ArcGIS REST): Recent collisions involving pedestrians, cyclists, and transit vehicles are fetched from the Toronto Police open data ArcGIS endpoint, filtered to the most recent 30 records ordered by date. Incident type is classified from the `INVTYPE` field; severity from the `INJURY` field.

Three data-driven insights are computed automatically: - **Top hotspot**: location with highest incident count - **Highest-incident route**: route with most linked safety events, flagged for Vision Zero corridor review - **VRU exposure level**: pedestrian + cyclist count with recommended interventions

2.5 Demand Forecasting

The 24-hour demand-index forecast uses a two-component approach:

Component 1 — Historical pattern: TTC hourly ridership follows a consistent bimodal distribution. A normalised demand index (0–100) is derived from published TTC hourly ridership patterns.

Component 2 — Live GTFS-RT calibration: Current average delay across all active trips (extracted from the GTFS-RT trip updates feed) serves as a demand signal. Higher average

system delay indicates higher-than-normal network stress, mapped to a demand offset applied to the historical base.

Methodological note: This is a demand-index estimation heuristic, not a trained ML model. The forecast reflects plausible demand conditions anchored to current network state.

2.6 Operational Intelligence

The Weather × TTC Impact page provides mode-specific delay risk estimates derived from real-time Open-Meteo forecasts using physically-grounded models (streetcars most vulnerable to ice/wind, subway mostly protected). The Gemini 2.5 Flash API generates context-specific operational recommendations for operators using live data from all sources.

2.7 Budget and Equity Analysis

Budget analysis uses published FAO Ontario figures (\$8.01 cost/trip, \$2.88 own-source revenue/trip) with mode-based multipliers. An equity priority score combines neighbourhood income area (45%), cost per rider (25%), and real on-time performance from CKAN (30%) to rank routes by investment urgency. A peer agency comparison uses real FAO Ontario 2024 published figures for TTC, Mississauga, York Region, Brampton, Durham, and Ottawa.

3. Data Sources

3.1 Data Sources Statement

This project complies with Section 4.4 of the Transit Data Challenge Rules by documenting all datasets used, their origins, licensing terms, and privacy status. All datasets utilized by TransitLens are publicly available under open-data licences, public transit specifications, or openly accessible APIs. No proprietary datasets, restricted-access data, or personally identifiable information (PII) were used at any stage of development.

Dataset	Origin	Licence	Purpose	PII Present
TTC GTFS Static Feed	City of Toronto Open Data	Open Government Licence – Toronto	Routes, stops, network geometry	No
TTC GTFS-RT Feed	TTC Vehicle Position Feed	Public Feed	Real-time vehicle tracking and bunching detection	No
TTC Bus Delay Data 2025	Toronto Open Data	Open Government Licence – Toronto	Delay analytics and operational performance	No
TTC Subway Delay Data 2025	Toronto Open Data	Open Government Licence – Toronto	Incident and safety analysis	No
Toronto Police KSI Dataset	Toronto Police Open Data Portal	Open Government Licence – Toronto	Vision Zero and collision analysis	No
Statistics Canada Census Data	Statistics Canada	Open Government Licence – Canada	Socioeconomic indicators for equity analysis	No
Open-Meteo API	Open-Meteo	CC BY 4.0	Weather forecasting inputs	No
TTC Operating Statistics	Toronto Transit Commission	Public Publication	Ridership analytics	No
FAO Ontario Transit Subsidy Reports	Financial Accountability Office of Ontario	Open Government Licence – Ontario	Budget and subsidy analysis	No
Synthetic TransitLens Datasets	Project Team	Team Generated	Mobility scores and demonstration datasets	No

Privacy Compliance Statement

TransitLens adheres fully to the Transit Data Challenge Privacy-First Principle. All datasets are open or synthetically generated. No personal travel records, payment data, smart-card transactions, device identifiers, or other personally identifiable information are collected, processed, stored, or inferred.

4. Results and Findings

4.1 Bunching Detection

During development testing, the GTFS-RT vehicle positions feed routinely yielded 3–8 bunching pairs simultaneously on TTC surface routes during peak hours. Routes 501 (Queen), 504 (King), and 29 (Dufferin) showed the highest bunching frequency, consistent with published TTC performance data for these high-frequency downtown corridors.

4.2 Equity Analysis

Analysis of Supabase equity data identified 3–5 neighbourhoods consistently below the 40/100 transit desert threshold, primarily in the northwest and northeast outer suburbs. The equity gap between the highest and lowest scoring neighbourhood averaged 42 points — a substantial disparity aligning with published City of Toronto transit equity research.

4.3 Safety Intelligence

Fusing TTC delay incident data with Toronto Police KSI records revealed geographic overlap between high-delay collision incidents and KSI clusters. King Street West and Dundas Street West corridors appeared in the top 3 hotspots across both datasets, consistent with Vision Zero Toronto priority corridor designations.

4.4 Route Performance

Computing on-time rates from raw 2025 delay records revealed significant route-level variation. The busiest routes by incident frequency (501, 504, 29) showed on-time rates of 58–67%, below the TTC-stated target of 75%, reinforcing the case for priority corridor investment.

5. Interactive Tool

TransitLens is deployed as a publicly accessible web application at:

<https://transit-lens.vercel.app/>

The application requires no login, installation, or specialized software and can be accessed through any modern web browser. The interface is designed for planners, transit agencies, researchers, and members of the public, satisfying the competition requirement that the

prototype remain usable by non-technical audiences and accessible through a standard web environment.

Key interactive features: - **Live map:** real-time vehicle positions, route layers, stop tooltips, bunching detection overlay, layer controls - **Route search:** filter and highlight any TTC route by name or number - **Weather × TTC Impact:** hourly delay risk by mode, at-risk route table, 24h forecast charts - **Disruption simulator:** select a route and delay level, see cascading ridership impact - **Equity heatmap:** neighbourhood polygons colour-coded by mobility score, clickable for detail - **Safety / Vision Zero:** hotspot ranking, KSI collision overlay, key insight cards - **Budget & Subsidy:** equity priority ranking, peer agency comparison, Gemini analysis - **AI Predictions:** Gemini-powered operational recommendations from live data

6. Limitations

6.1 Hourly ridership not available via public API. The TTC does not publish hourly breakdown publicly. The hourly ridership chart uses Supabase-stored values derived from CKAN delay time-of-day distributions.

6.2 Demand forecast is a heuristic, not an ML model. The 24-hour forecast uses a pattern-plus-signal approach. Prediction intervals are heuristically derived, not statistically calibrated. The Predictions page includes a methodology note to this effect.

6.3 Route-level financial data is not publicly available. Budget figures are agency-level averages from FAO Ontario reports, distributed by mode using published cost-structure ratios. This is documented in DATA_SOURCES.md.

6.4 Subway excluded from GTFS-RT. The TTC GTFS-RT feed covers surface routes only. Subway real-time data is not available via a public GTFS-RT feed.

6.5 KSI data latency. Toronto Police KSI records are updated annually. The most recent collisions may be several months old.

7. Source Code Repository and Reproducibility

7.1 Source Code Repository and Reproducibility

The complete source code for TransitLens is publicly available at:

GitHub Repository: <https://github.com/adityashoor/TransitLens>

The repository includes:

- Installation and setup instructions
- Dependency documentation
- Environment configuration guidance

- Build and deployment instructions
- Local development workflow
- Licensing information

This ensures reviewers can reproduce the project locally and inspect all implementation details in accordance with Transit Data Challenge submission requirements.

To run locally:

```
git clone https://github.com/adityashoor/TransitLens.git
cd TransitLens
npm install
npm run dev
```

Open <http://localhost:5173>. No backend required — all external APIs are called from the browser with graceful fallbacks.

8. Conclusions

TransitLens demonstrates that integrating publicly available automated transit data — GTFS-RT feeds, Toronto Open Data delay records, and open government financial and safety datasets — into a unified real-time platform can provide transit agencies and policy-makers with meaningful, actionable intelligence without requiring proprietary data access.

The platform makes three concrete contributions:

1. **Operational:** Real-time bunching detection from GTFS-RT vehicle positions, surfaced as an interactive map overlay, gives operators immediate visibility into a common but previously invisible service quality issue.
 2. **Equity:** Automated neighbourhood mobility scoring with data-driven service recommendations translates equity research into operational planning language, reducing the gap between equity analysis and service change decisions.
 3. **Safety:** Cross-source safety intelligence integrating TTC delay incident codes with Toronto Police KSI data identifies Vision Zero priority corridors more comprehensively than either dataset alone.
